

▼ Creating a Sentiment Analysis Web App

Using PyTorch and SageMaker

Deep Learning Nanodegree Program | Deployment

Now that we have a basic understanding of how SageMaker works we will try to use it to construct a web application. The goal will be to have a simple web page which a user can use to enter a movie review. The web page will use a SageMaker model which will predict the sentiment of the entered review.

Instructions

Some template code has already been provided for you, and you will need to implement additional functionality in this notebook. You will not need to modify the included code beyond what is requested. Sections that begin with `# TODO: ...` comment. Please be sure to read the instructions for each section.

In addition to implementing code, there will be questions for you to answer which relate to the task at hand. Where you will answer a question is preceded by a '**Question:**' header. Carefully read each question and answer it by editing the Markdown cell.

Note: Code and Markdown cells can be executed using the **Shift+Enter** keyboard shortcut. In addition, you can typically clicking it (double-click for Markdown cells) or by pressing **Enter** while it is highlighted.

General Outline

Recall the general outline for SageMaker projects using a notebook instance.

1. Download or otherwise retrieve the data.
2. Process / Prepare the data.
3. Upload the processed data to S3.
4. Train a chosen model.
5. Test the trained model (typically using a batch transform job).
6. Deploy the trained model.
7. Use the deployed model.

For this project, you will be following the steps in the general outline with some modifications.

First, you will not be testing the model in its own step. You will still be testing the model, however, you will be testing the model by sending the test data to it. One of the reasons for doing this is so that you can ensure the model is working correctly before moving forward.

In addition, you will deploy and use your trained model a second time. In the second iteration you will use a model that is deployed by including some of your own code. In addition, your newly deployed model will be used in the next iteration.

▼ Step 1: Downloading the data

As in the XGBoost in SageMaker notebook, we will be using the [IMDb dataset](#)

Maas, Andrew L., et al. [Learning Word Vectors for Sentiment Analysis](#). In *Proceedings of the 49th Association for Computational Linguistics: Human Language Technologies*. Association for Computational Linguistics, 2011.

```
%mkdir ../data
!wget -O ../data/aclImdb_v1.tar.gz http://ai.stanford.edu/~amaas/data/sentiment/aclImdb_v1.tar.gz
!tar -zxvf ../data/aclImdb_v1.tar.gz -C ../data
```

 mkdir: cannot create directory '../data': File exists

```

▼ Step 2: Preparing and Processing the data

Also, as in the XGBoost notebook, we will be doing some initial data processing. The first few steps are to load the data. To begin with, we will read in each of the reviews and combine them into a single input structure. Then we will split the data into a training set and a testing set.

```
import os
import glob

def read_imdb_data(data_dir='../data/aclImdb'):
    data = {}
    labels = {}

    for data_type in ['train', 'test']:
        data[data_type] = {}
        labels[data_type] = {}

        for sentiment in ['pos', 'neg']:
            data[data_type][sentiment] = []
            labels[data_type][sentiment] = []
```

```

labels[data_type][sentiment] = []

path = os.path.join(data_dir, data_type, sentiment, '*.txt')
files = glob.glob(path)

for f in files:
    with open(f) as review:
        data[data_type][sentiment].append(review.read())
        # Here we represent a positive review by '1' and a negative review by '0'
        labels[data_type][sentiment].append(1 if sentiment == 'pos' else 0)

assert len(data[data_type][sentiment]) == len(labels[data_type][sentiment])
    "{}/{} data size does not match labels size".format(data_type, sentiment)

return data, labels

```

```

data, labels = read_imdb_data()
print("IMDB reviews: train = {} pos / {} neg, test = {} pos / {} neg".format(
    len(data['train']['pos']), len(data['train']['neg']),
    len(data['test']['pos']), len(data['test']['neg'])))

```

IMDB reviews: train = 12500 pos / 12500 neg, test = 12500 pos / 12500 neg

Now that we've read the raw training and testing data from the downloaded dataset, we will combine and shuffle the resulting records.

```

from sklearn.utils import shuffle

def prepare_imdb_data(data, labels):
    """Prepare training and test sets from IMDB movie reviews."""

    #Combine positive and negative reviews and labels
    data_train = data['train']['pos'] + data['train']['neg']
    data_test = data['test']['pos'] + data['test']['neg']
    labels_train = labels['train']['pos'] + labels['train']['neg']
    labels_test = labels['test']['pos'] + labels['test']['neg']

    #Shuffle reviews and corresponding labels within training and test sets
    data_train, labels_train = shuffle(data_train, labels_train)
    data_test, labels_test = shuffle(data_test, labels_test)

    # Return a unified training data, test data, training labels, test labels
    return data_train, data_test, labels_train, labels_test

train_X, test_X, train_y, test_y = prepare_imdb_data(data, labels)
print("IMDB reviews (combined): train = {}, test = {}".format(len(train_X), len(test_X)))

```

 IMDb reviews (combined): train = 25000, test = 25000

Now that we have our training and testing sets unified and prepared, we should do a quick check and be trained on. This is generally a good idea as it allows you to see how each of the further processing ensures that the data has been loaded correctly.

```
print(train_X[100])
print(train_y[100])
```

 All I could think of while watching this movie was B-grade slop. Many have spoken
0

The first step in processing the reviews is to make sure that any html tags that appear should be removed from the input, that way words such as *entertained* and *entertaining* are considered the same with regard to ser

```
import nltk
from nltk.corpus import stopwords
from nltk.stem.porter import *

import re
from bs4 import BeautifulSoup

def review_to_words(review):
    nltk.download("stopwords", quiet=True)
    stemmer = PorterStemmer()

    text = BeautifulSoup(review, "html.parser").get_text() # Remove HTML tags
    text = re.sub(r"[^a-zA-Z0-9]", " ", text.lower()) # Convert to lower case
    words = text.split() # Split string into words
    words = [w for w in words if w not in stopwords.words("english")] # Remove stopwords
    words = [PorterStemmer().stem(w) for w in words] # stem

    return words
```

The `review_to_words` method defined above uses `BeautifulSoup` to remove any html tags that appear in the reviews. As a check to ensure we know how everything is working, try applying `review_to_words` to the training set.

```
# TODO: Apply review_to_words to a review (train_X[100] or any other review)
review_to_words(train_X[220])
```

```
[ 'get',
  'amaz',
  'bad',
  'film',
  'world',
  'anybodi',
  'could',
  'rais',
  'money',
  'make',
  'kind',
  'crap',
  'absolut',
  'talent',
  'includ',
  'film',
  'crappi',
  'script',
```

Question: Above we mentioned that `review_to_words` method removes html formatting and allows for example, converting *entertained* and *entertaining* into *entertain* so that they are treated as though anything, does this method do to the input?

```
# This is formatted as code
```

Answer: the `review_to_words` method removes all punctuation and converts all the words to lower case

The method below applies the `review_to_words` method to each of the reviews in the training and test results. This is because performing this processing step can take a long time. This way if you are unavailable during the current session, you can come back without needing to process the data a second time.

```
import pickle

cache_dir = os.path.join("../cache", "sentiment_analysis") # where to store cache files
os.makedirs(cache_dir, exist_ok=True) # ensure cache directory exists

def preprocess_data(data_train, data_test, labels_train, labels_test,
                    cache_dir=cache_dir, cache_file="preprocessed_data.pkl"):
    """Convert each review to words; read from cache if available."""

    # If cache_file is not None, try to read from it first
    cache_data = None
    if cache_file is not None:
        try:
            with open(os.path.join(cache_dir, cache_file), "rb") as f:
                cache_data = pickle.load(f)
            print("Read preprocessed data from cache file:", cache_file)
        except:
            pass # unable to read from cache, but that's okay
```

```
# If cache is missing, then do the heavy lifting
if cache_data is None:
    # Preprocess training and test data to obtain words for each review
    #words_train = list(map(review_to_words, data_train))
    #words_test = list(map(review_to_words, data_test))
    words_train = [review_to_words(review) for review in data_train]
    words_test = [review_to_words(review) for review in data_test]

    # Write to cache file for future runs
    if cache_file is not None:
        cache_data = dict(words_train=words_train, words_test=words_test,
                           labels_train=labels_train, labels_test=labels_test)
        with open(os.path.join(cache_dir, cache_file), "wb") as f:
            pickle.dump(cache_data, f)
        print("Wrote preprocessed data to cache file:", cache_file)
    else:
        # Unpack data loaded from cache file
        words_train, words_test, labels_train, labels_test = (cache_data['words_train'],
                                                                cache_data['words_test'],
                                                                cache_data['labels_train'],
                                                                cache_data['labels_test'])

return words_train, words_test, labels_train, labels_test
```

```
# Preprocess data
```

```
train_X, test_X, train_y, test_y = preprocess_data(train_X, test_X, train_y, test_y)
```

```
Read preprocessed data from cache file: preprocessed_data.pkl
```

▼ Transform the data

In the XGBoost notebook we transformed the data from its word representation to a bag-of-words feature. In this notebook we will construct a feature representation which is very similar. To integer. Of course, some of the words that appear in the reviews occur very infrequently and so likely for the purposes of sentiment analysis. The way we will deal with this problem is that we will fix the size of our vocabulary to include the words that appear most frequently. We will then combine all of the infrequent words into a single category and label it as 1.

Since we will be using a recurrent neural network, it will be convenient if the length of each review is the same. We will truncate our reviews and then pad short reviews with the category 'no word' (which we will label 0) and truncate the rest to the same length.

▼ (TODO) Create a word dictionary

To begin with, we need to construct a way to map words that appear in the reviews to integers. Here we will use a dictionary to map words to integers. We will use the 'no word' and 'infrequent' categories to be 5000 but you may wish to change this to see how it affects the model.

TODO: Complete the implementation for the `build_dict()` method below. Note that even though we only want to construct a mapping for the most frequently appearing 4998 words. This is because special labels 0 for 'no word' and 1 for 'infrequent word'.

```
import numpy as np
```

```
def build_dict(data, vocab_size = 5000):
    """Construct and return a dictionary mapping each of the most frequently appearing
    words to an index. The index 0 is reserved for 'no word' and index 1 is reserved for 'infrequent word'.

word_count = {} # A dict storing the words that appear in the reviews along with their counts

for review in data:

for word in review:

if word in word_count:

word_count[word] += 1

else:

word_count[word] = 1

# Sort the words found in `data` so that sorted_words[0] is the most frequently appearing word.

# sorted_words[-1] is the least frequently appearing word.

sorted_words = sorted(word_count.items(), key = lambda x: x[1], reverse=True)

sorted_words = [sorted_word for sorted_word, _ in sorted_words]

word_dict = {} # This is what we are building, a dictionary that translates words to indices

for idx, word in enumerate(sorted_words[:vocab_size - 2]):

word_dict[word] = idx + 2

return word_dict

```

```
word_dict = build_dict(train_X)
```

```
print('Total:', len(word_dict))
```

 Total: 4998

Question: What are the five most frequently appearing (tokenized) words in the training set? Does it make sense for these words to appear frequently in the training set?

Answer: yes it does they all are words you would expect in a movie review

```
# TODO: Use this space to determine the five most frequently appearing words in the training set
most_freq_number = 5
```

```

count = 0
for word in list(enumerate(word_dict)):
    if count < most_freq_number:
        print('Most frequently appearing word number:',str(count + 1),':',word[1])
        count += 1
    else:
        break

```

```

Most frequently appearing word number: 1 : movi
Most frequently appearing word number: 2 : film
Most frequently appearing word number: 3 : one
Most frequently appearing word number: 4 : like
Most frequently appearing word number: 5 : time

```

▼ Save word_dict

Later on when we construct an endpoint which processes a submitted review we will need to make use of the word dictionary created. As such, we will save it to a file now for future use.

```

data_dir = '../data/pytorch' # The folder we will use for storing data
if not os.path.exists(data_dir): # Make sure that the folder exists
    os.makedirs(data_dir)

with open(os.path.join(data_dir, 'word_dict.pkl'), "wb") as f:
    pickle.dump(word_dict, f)

```

▼ Transform the reviews

Now that we have our word dictionary which allows us to transform the words appearing in the review and convert our reviews to their integer sequence representation, making sure to pad or truncate to a fixed length.

```

def convert_and_pad(word_dict, sentence, pad=500):
    NOWORD = 0 # We will use 0 to represent the 'no word' category
    INFREQ = 1 # and we use 1 to represent the infrequent words, i.e., words not appearing in the dictionary

    working_sentence = [NOWORD] * pad

    for word_index, word in enumerate(sentence[:pad]):
        if word in word_dict:
            working_sentence[word_index] = word_dict[word]
        else:
            working_sentence[word_index] = INFREQ

    return working_sentence, min(len(sentence), pad)

def convert_and_pad_data(word_dict, data, pad=500):
    result = []
    lengths = []

```

```

for sentence in data:
    converted, leng = convert_and_pad(word_dict, sentence, pad)
    result.append(converted)
    lengths.append(leng)

return np.array(result), np.array(lengths)

```

```

train_X, train_X_len = convert_and_pad_data(word_dict, train_X)
test_X, test_X_len = convert_and_pad_data(word_dict, test_X)

```

As a quick check to make sure that things are working as intended, check to see what one of the reviews having been processed. Does this look reasonable? What is the length of a review in the training set?

```

# Use this cell to examine one of the processed reviews to make sure everything is working
len(train_X[0])

```

 500

Question: In the cells above we use the `preprocess_data` and `convert_and_pad_data` methods to process the data. Why or why not might this be a problem?

Answer: `preprocess_data` is performed so that each review has the `review_to_words` method applied, done so that it loads quicker.

`convert_and_pad` method is used to normalise the reviews.

▼ Step 3: Upload the data to S3

As in the XGBoost notebook, we will need to upload the training dataset to S3 in order for our training locally and we will upload to S3 later on.

Save the processed training dataset locally

It is important to note the format of the data that we are saving as we will need to know it when we write a row of the dataset has the form `label, length, review[500]` where `review[500]` is a sequence of 500 words from the review.

```

import pandas as pd

pd.concat([pd.DataFrame(train_y), pd.DataFrame(train_X_len), pd.DataFrame(train_X)], axis=1)
.to_csv(os.path.join(data_dir, 'train.csv'), header=False, index=False)

```

▼ Uploading the training data

Next, we need to upload the training data to the SageMaker default S3 bucket so that we can provide :

```
import sagemaker

sagemaker_session = sagemaker.Session()

bucket = sagemaker_session.default_bucket()
prefix = 'sagemaker/sentiment_rnn'

role = sagemaker.get_execution_role()

input_data = sagemaker_session.upload_data(path=data_dir, bucket=bucket, key_prefix=pr
```

NOTE: The cell above uploads the entire contents of our data directory. This includes the `word_dict`. this later on when we create an endpoint that accepts an arbitrary review. For now, we will just take no directory (and so also in the S3 training bucket) and that we will need to make sure it gets saved in the

▼ Step 4: Build and Train the PyTorch Model

In the XGBoost notebook we discussed what a model is in the SageMaker framework. In particular, a model consists of:

- Model Artifacts,
- Training Code, and
- Inference Code,

each of which interact with one another. In the XGBoost example we used training and inference code will still be using containers provided by Amazon with the added benefit of being able to include our own code.

We will start by implementing our own neural network in PyTorch along with a training script. For the purpose of this notebook, we will create a `model.py` file, inside of the `train` folder. You can see the provided code below.

```
!pygmentize train/model.py
```

```

import torch.nn as nn

class LSTMClassifier(nn.Module):
    """
    This is the simple RNN model we will be using to perform Sentiment Analysis.
    """

    def __init__(self, embedding_dim, hidden_dim, vocab_size):
        """
        Initialize the model by settingg up the various layers.
        """
        super(LSTMClassifier, self).__init__()

        self.embedding = nn.Embedding(vocab_size, embedding_dim, padding_idx=0)
        self.lstm = nn.LSTM(embedding_dim, hidden_dim)
        self.dense = nn.Linear(in_features=hidden_dim, out_features=1)
        self.sig = nn.Sigmoid()

        self.word_dict = None

```

The important takeaway from the implementation provided is that there are three parameters that we performance of our model. These are the embedding dimension, the hidden dimension and the size of the vocabulary. To make these parameters configurable in the training script so that if we wish to modify them we do not see how to do this later on. To start we will write some of the training code in the notebook so that we arise.

First we will load a small portion of the training data set to use as a sample. It would be very time consuming to load the entire dataset completely in the notebook as we do not have access to a gpu and the compute instance that we are using. However, we can work on a small bit of the data to get a feel for how our training script is behaving.

```

import torch
import torch.utils.data

# Read in only the first 250 rows
train_sample = pd.read_csv(os.path.join(data_dir, 'train.csv'), header=None, names=None)

# Turn the input pandas dataframe into tensors
train_sample_y = torch.from_numpy(train_sample[[0]].values).float().squeeze()
train_sample_X = torch.from_numpy(train_sample.drop([0], axis=1).values).long()

# Build the dataset
train_sample_ds = torch.utils.data.TensorDataset(train_sample_X, train_sample_y)
# Build the dataloader
train_sample_dl = torch.utils.data.DataLoader(train_sample_ds, batch_size=50)

```

▼ (TODO) Writing the training method

Next we need to write the training code itself. This should be very similar to training methods that you have seen in previous models. We will leave any difficult aspects such as model saving / loading and parameter loading until later.

```
def train(model, train_loader, epochs, optimizer, loss_fn, device):
    for epoch in range(1, epochs + 1):
        model.train()
        total_loss = 0
        for batch in train_loader:
            batch_X, batch_y = batch

            batch_X = batch_X.to(device)
            batch_y = batch_y.to(device)

            # TODO: Complete this train method to train the model provided.

            optimizer.zero_grad()
            out = model.forward(batch_X)
            loss = loss_fn(out, batch_y)
            loss.backward()
            optimizer.step()

        total_loss += loss.data.item()
    print("Epoch: {}, BCELoss: {}".format(epoch, total_loss / len(train_loader)))
```

Supposing we have the training method above, we will test that it is working by writing a bit of code in method on the small sample training set that we loaded earlier. The reason for doing this in the notebook is to fix any errors that arise early when they are easier to diagnose.

```
import torch.optim as optim
from train.model import LSTMClassifier

device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
model = LSTMClassifier(32, 100, 5000).to(device)
optimizer = optim.Adam(model.parameters())
loss_fn = torch.nn.BCELoss()

train(model, train_sample_dl, 5, optimizer, loss_fn, device)
```

```
Epoch: 1, BCELoss: 0.6945010185241699
Epoch: 2, BCELoss: 0.684006130695343
Epoch: 3, BCELoss: 0.6749066114425659
Epoch: 4, BCELoss: 0.6650547742843628
Epoch: 5, BCELoss: 0.6532368540763855
```

In order to construct a PyTorch model using SageMaker we must provide SageMaker with a training script directory which will be copied to the container and from which our training code will be run. When the script is run, it will copy the uploaded directory (if there is one) for a `requirements.txt` file and install any required Python libraries.

▼ (TODO) Training the model

When a PyTorch model is constructed in SageMaker, an entry point must be specified. This is the Python model is trained. Inside of the `train` directory is a file called `train.py` which has been provided and code to train our model. The only thing that is missing is the implementation of the `train()` method

TODO: Copy the `train()` method written above and paste it into the `train/train.py` file where required.

The way that SageMaker passes hyperparameters to the training script is by way of arguments. These are passed in the training script. To see how this is done take a look at the provided `train/train.py` file.

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(entry_point="train.py",
                    source_dir="train",
                    role=role,
                    framework_version='0.4.0',
                    train_instance_count=1,
                    train_instance_type='ml.p2.xlarge',
                    hyperparameters={
                        'epochs': 10,
                        'hidden_dim': 200,
                    })

estimator.fit({'training': input_data})
```

```

▼ Step 5: Testing the model

As mentioned at the top of this notebook, we will be testing this model by first deploying it and then sending a request to the endpoint. We will do this so that we can make sure that the deployed model is working correctly.

Step 6: Deploy the model for testing

Now that we have trained our model, we would like to test it to see how it performs. Currently our model takes a `review_length`, `review[500]` where `review[500]` is a sequence of 500 integers which describe the review, and returns a prediction using `word_dict`. Fortunately for us, SageMaker provides built-in inference code for models with similar structure.

There is one thing that we need to provide, however, and that is a function which loads the saved model. We will create a function `model_fn()` and takes as its only parameter a path to the directory where the model artifacts are stored. This function will return the python file which we specified as the entry point. In our case the model loading function has been implemented as follows.

NOTE: When the built-in inference code is run it must import the `model_fn()` method from the `train.py` file. This is wrapped in a main guard (ie, `if __name__ == '__main__':`).

Since we don't need to change anything in the code that was uploaded during training, we can simply deploy the model as is.

NOTE: When deploying a model you are asking SageMaker to launch a compute instance that will wait for you to provide a request. The compute instance will continue to run until *you* shut it down. This is important to know since the cost of the instance is charged for as long as it has been running for.

In other words **If you are no longer using a deployed endpoint, shut it down!**

TODO: Deploy the trained model.

```
# TODO: Deploy the trained model
predictor = estimator.deploy(initial_instance_count=1, instance_type='ml.m4.xlarge')
```

 -----!

▼ Step 7 - Use the model for testing

Once deployed, we can read in the test data and send it off to our deployed model to get some results determine how accurate our model is.

```
test_X = pd.concat([pd.DataFrame(test_X_len), pd.DataFrame(test_X)], axis=1)

# We split the data into chunks and send each chunk separately, accumulating the result

def predict(data, rows=512):
    split_array = np.array_split(data, int(data.shape[0] / float(rows) + 1))
    predictions = np.array([])
    for array in split_array:
        predictions = np.append(predictions, predictor.predict(array))

    return predictions

predictions = predict(test_X.values)
predictions = [round(num) for num in predictions]

from sklearn.metrics import accuracy_score
accuracy_score(test_y, predictions)
```

 0.8566

Question: How does this model compare to the XGBoost model you created earlier? Why might these dataset? Which do *you* think is better for sentiment analysis?

Answer: it's higher than the XGBoost model so I would choose this one

▼ (TODO) More testing

We now have a trained model which has been deployed and which we can send processed reviews to sentiment. However, ultimately we would like to be able to send our model an unprocessed review. Th itself as a string. For example, suppose we wish to send the following review to our model.

```
test_review = "The simplest pleasures in life are the best, and this film is one of the
```

The question we now need to answer is, how do we send this review to our model?

Recall in the first section of this notebook we did a bunch of data processing to the IMDb dataset. In particular, we processed the provided reviews.

- Removed any html tags and stemmed the input
- Encoded the review as a sequence of integers using `word_dict`

In order to process the review we will need to repeat these two steps.

TODO: Using the `review_to_words` and `convert_and_pad` methods from section one, convert `test_review` into a form suitable to send to our model. Remember that our model expects input of the form `review_length, review_words`.

```
# TODO: Convert test_review into a form usable by the model and save the results in test_data
test_data = [np.array(convert_and_pad(word_dict, review_to_words(test_review)))]
test_data
```

```
[array([ 1, 1374, 50, 53, 3, 4, 878, 173, 392, 682, 29,
        723, 2, 4409, 275, 2075, 1060, 760, 1, 582, 0, 0,
        0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
        0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
        0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
        0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
        0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
        0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
        0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
        0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
        0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0.]
```

Now that we have processed the review, we can send the resulting array to our model to predict the sentiment.

```
0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0.]
```

```
predictor.predict(test_data)
```

```
array(0.6177029, dtype=float32)
```

```
0 0 0 0 0 0 0 0 0 0 0
```

Since the return value of our model is close to 1, we can be certain that the review we submitted is positive.

```
0 0 0 0 0 0 0 0 0 0 0
```

▼ Delete the endpoint

Of course, just like in the XGBoost notebook, once we've deployed an endpoint it continues to run until we stop it. Since we are not using our endpoint for now, we can delete it.

```
0 0 0 0 0 0 0 0 0 0 0
```

```
estimator.delete_endpoint()
```

```
0 0 0 0 0 0 0 0 0 0 0
```

▼ Step 6 (again) - Deploy the model for the web app

Now that we know that our model is working, it's time to create some custom inference code so that we can use it to predict the sentiment of reviews that have not been processed and have it determine the sentiment of the review.

As we saw above, by default the estimator which we created, when deployed, will use the entry script `entry.py` to create the model. However, since we now wish to accept a string as input and our model expects a `numpy` array, we need to write a custom inference code.

We will store the code that we write in the `serve` directory. Provided in this directory is the `model.py` file which contains the `review_to_words` and `convert_and_pad` pre-processing functions, and `predict.py`, the file which will contain our custom inference code. Note also that we need to tell SageMaker what Python libraries are required by our custom inference code.

When deploying a PyTorch model in SageMaker, you are expected to provide four functions which the estimator will use:

- `model_fn`: This function is the same function that we used in the training script and it tells SageMaker how to load the model.
- `input_fn`: This function receives the raw serialized input that has been sent to the model's endpoint and makes the input available for the inference code.

- `output_fn`: This function takes the output of the inference code and its job is to serialize this o model's endpoint.
- `predict_fn`: The heart of the inference script, this is where the actual prediction is done and is complete.

For the simple website that we are constructing during this project, the `input_fn` and `output_fn` m only require being able to accept a string as input and we expect to return a single value as output. Yo complex application the input or output may be image data or some other binary data which would re

(TODO) Writing inference code

Before writing our custom inference code, we will begin by taking a look at the code which has been p

```
!pygmentize serve/predict.py
```

```

import argparse
import json
import os
import pickle
import sys
import sagemaker_containers
import pandas as pd
import numpy as np
import torch
import torch.nn as nn
import torch.optim as optim
import torch.utils.data

from model import LSTMClassifier

from utils import review_to_words, convert_and_pad

def model_fn(model_dir):
    """Load the PyTorch model from the `model_dir` directory."""
    print("Loading model.")

    # First, load the parameters used to create the model.
    model_info = {}
    model_info_path = os.path.join(model_dir, 'model_info.pth')
    with open(model_info_path, 'rb') as f:
        model_info = torch.load(f)

    print("model_info: {}".format(model_info))

    # Determine the device and construct the model.
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
    model = LSTMClassifier(model_info['embedding_dim'], model_info['hidden_dim'],

    # Load the store model parameters.
    model_path = os.path.join(model_dir, 'model.pth')
    with open(model_path, 'rb') as f:
        model.load_state_dict(torch.load(f))

    # Load the saved word_dict.
    word_dict_path = os.path.join(model_dir, 'word_dict.pkl')
    with open(word_dict_path, 'rb') as f:
        model.word_dict = pickle.load(f)

    model.to(device).eval()

    print("Done loading model.")
    return model

def input_fn(serialized_input_data, content_type):
    print('Deserializing the input data.')
    if content_type == 'text/plain':
        data = serialized_input_data.decode('utf-8')
        return data
    raise Exception('Requested unsupported ContentType in content_type: ' + conte

def output_fn(prediction_output, accept):
    print('Serializing the generated output.')

```

As mentioned earlier, the `model_fn` method is the same as the one provided in the training code and are very simple and your task will be to complete the `predict_fn` method. Make sure that you save to `serve` directory.

TODO: Complete the `predict_fn()` method in the `serve/predict.py` file.

```
if model.word_dict is None:
```

▼ Deploying the model

Now that the custom inference code has been written, we will create and deploy our model. To begin we create a `PyTorchModel` object which points to the model artifacts created during training and also points to the `predict.py` file. Then we can call the `deploy` method to launch the deployment container.

NOTE: The default behaviour for a deployed PyTorch model is to assume that any input passed to the `predict` method will be a string so we need to construct a simple wrapper around the `RealTimePredictor` class. In a more complicated situation you may want to provide a serialization object, for example if you wanted

```
data_loader = torch.load(data_dir, data_dir)
```

```
from sagemaker.predictor import RealTimePredictor
from sagemaker.pytorch import PyTorchModel
```

```
class StringPredictor(RealTimePredictor):
    def __init__(self, endpoint_name, sagemaker_session):
        super(StringPredictor, self).__init__(endpoint_name, sagemaker_session, container)
```

```
model = PyTorchModel(model_data=estimator.model_data,
                      role = role,
                      framework_version='0.4.0',
                      entry_point='predict.py',
                      source_dir='serve',
                      predictor_cls=StringPredictor)
predictor = model.deploy(initial_instance_count=1, instance_type='ml.m4.xlarge')
```

-----!

▼ Testing the model

Now that we have deployed our model with the custom inference code, we should test to see if everything works by loading the first 250 positive and negative reviews and send them to the endpoint, then collect the results. Some of the data is that the amount of time it takes for our model to process the input and then perform the entire data set would be prohibitive.

```
import glob
```

```
def test_reviews(data_dir='../data/aclImdb', stop=250):
```

```

results = []
ground = []

# We make sure to test both positive and negative reviews
for sentiment in ['pos', 'neg']:

    path = os.path.join(data_dir, 'test', sentiment, '*.txt')
    files = glob.glob(path)

    files_read = 0

    print('Starting ', sentiment, ' files')

    # Iterate through the files and send them to the predictor
    for f in files:
        with open(f) as review:
            # First, we store the ground truth (was the review positive or negative)
            if sentiment == 'pos':
                ground.append(1)

            else:
                ground.append(0)
            # Read in the review and convert to 'utf-8' for transmission via HTTP
            review_input = review.read().encode('utf-8')
            # Send the review to the predictor and store the results
            results.append(float(predictor.predict(review_input)))

    # Sending reviews to our endpoint one at a time takes a while so we
    # only send a small number of reviews
    files_read += 1
    if files_read == stop:
        break

return ground, results

```

```
ground, results = test_reviews()
```

```
Starting pos files
Starting neg files
```

```

from sklearn.metrics import accuracy_score
accuracy_score(ground, results)

```

```
0.864
```

As an additional test, we can try sending the `test_review` that we looked at earlier.

```
predictor.predict(test_review)
```

Now that we know our endpoint is working as expected, we can set up the web page that will interact project now, make sure to skip down to the end of this notebook and shut down your endpoint. You can

▼ Step 7 (again): Use the model for the web app

TODO: This entire section and the next contain tasks for you to complete, mostly using the AWS CLI

So far we have been accessing our model endpoint by constructing a predictor object which uses the object to perform inference. What if we wanted to create a web app which accessed our model? That is not possible since in order to access a SageMaker endpoint the app would first have to authenticate via access to SageMaker endpoints. However, there is an easier way! We just need to use some additional

The diagram above gives an overview of how the various services will work together. On the far right is which is deployed using SageMaker. On the far left is our web app that collects a user's movie review, negative sentiment in return.

In the middle is where some of the magic happens. We will construct a Lambda function, which you can function that can be executed whenever a specified event occurs. We will give this function permission SageMaker endpoint.

Lastly, the method we will use to execute the Lambda function is a new endpoint that we will create using url that listens for data to be sent to it. Once it gets some data it will pass that data on to the Lambda Lambda function returns. Essentially it will act as an interface that lets our web app communicate with

Setting up a Lambda function

The first thing we are going to do is set up a Lambda function. This Lambda function will be executed it. When it is executed it will receive the data, perform any sort of processing that is required, send the endpoint we've created and then return the result.

Part A: Create an IAM Role for the Lambda function

Since we want the Lambda function to call a SageMaker endpoint, we need to make sure that it has permission to construct a role that we can later give the Lambda function.

Using the AWS Console, navigate to the **IAM** page and click on **Roles**. Then, click on **Create role**. Make a trusted entity selected and choose **Lambda** as the service that will use this role, then click **Next: Permissions**

In the search box type `sagemaker` and select the check box next to the **AmazonSageMakerFullAccess**

Lastly, give this role a name. Make sure you use a name that you will remember later on, for example : **Create role**.

Part B: Create a Lambda function

Now it is time to actually create the Lambda function.

Using the AWS Console, navigate to the AWS Lambda page and click on **Create a function**. When you **Author from scratch** is selected. Now, name your Lambda function, using a name that you will remember `sentiment_analysis_func`. Make sure that the **Python 3.6** runtime is selected and then choose the **Then, click on Create Function**.

On the next page you will see some information about the Lambda function you've just created. If you which you can write the code that will be executed when your Lambda function is triggered. In our exa

```
# We need to use the low-level library to interact with SageMaker since the SageMaker API
# is not available natively through Lambda.
import boto3

def lambda_handler(event, context):

    # The SageMaker runtime is what allows us to invoke the endpoint that we've created.
    runtime = boto3.Session().client('sagemaker-runtime')

    # Now we use the SageMaker runtime to invoke our endpoint, sending the review we were give
    response = runtime.invoke_endpoint(EndpointName = '**ENDPOINT NAME HERE**',      # The name
                                      ContentType = 'text/plain',                  # The data
                                      Body = event['body'])                        # The actual

    # The response is an HTTP response whose body contains the result of our inference
    result = response['Body'].read().decode('utf-8')

    return {
        'statusCode' : 200,
        'headers' : { 'Content-Type' : 'text/plain', 'Access-Control-Allow-Origin' : '*' },
        'body' : result
    }
```

Once you have copy and pasted the code above into the Lambda code editor, replace the `**ENDPOINT` the endpoint that we deployed earlier. You can determine the name of the endpoint using the code cel

```
predictor.endpoint
```

Once you have added the endpoint name to the Lambda function, click on **Save**. Your Lambda function create a way for our web app to execute the Lambda function.

Setting up API Gateway

Now that our Lambda function is set up, it is time to create a new API using API Gateway that will trigger the function we created earlier.

Using AWS Console, navigate to **Amazon API Gateway** and then click on **Get started**.

On the next page, make sure that **New API** is selected and give the new api a name, for example, `sentiment-classifier`. Then click on **Create API**.

Now we have created an API, however it doesn't currently do anything. What we want it to do is to trigger the Lambda function we created earlier.

Select the **Actions** dropdown menu and click **Create Method**. A new blank method will be created, select the **POST** method and then click on the check mark beside it.

For the integration point, make sure that **Lambda Function** is selected and click on the **Use Lambda Proxy** integration type. This ensures that the data that is sent to the API is then sent directly to the Lambda function with no processing. It also ensures that the Lambda function returns a proper response object as it will also not be processed by API Gateway.

Type the name of the Lambda function you created earlier into the **Lambda Function** text entry box and click on the dropdown arrow. A pop-up box that then appears, giving permission to API Gateway to invoke the Lambda function you created.

The last step in creating the API Gateway is to select the **Actions** dropdown and click on **Deploy API**. This will create a new deployment stage and name it anything you like, for example `prod`.

You have now successfully set up a public API to access your SageMaker model. Make sure to copy the URL of your newly created public API as this will be needed in the next step. This URL can be found at the top of the page next to the text **Invoke URL**.

▼ Step 4: Deploying our web app

Now that we have a publicly available API, we can start using it in a web app. For our purposes, we have already created a simple web app that can make use of the public api you created earlier.

In the `website` folder there should be a file called `index.html`. Download the file to your computer and open it in a text editor of your choice. There should be a line which contains ****REPLACE WITH PUBLIC API URL****. Replace this string with the URL of the API you created in the last step and then save the file.

Now, if you open `index.html` on your local computer, your browser will behave as a local web server and the web app will be able to interact with your SageMaker model.

If you'd like to go further, you can host this html file anywhere you'd like, for example using github or heroku. If you have done this you can share the link with anyone you'd like and have them play with it too!

Important Note In order for the web app to communicate with the SageMaker endpoint, the endpoint must be running. This means that you are paying for it. Make sure that the endpoint is running when you use it.
